A B S T R A C T

The peculiarities of the negative refraction in periodic multilayered antiferromagnet–semiconductor nanostructures are investigated in the presence of an external magnetic field parallel to the plane of the layers. Effective material tensors are obtained using method of anisotropic homogeneous medium. Dispersion and energetic relations for the mixed magnon–plasmon polaritons are investigated in the case of the Voigt geometry. Frequency regions of anomalous dispersion are found and studied in various regimes of the applied magnetic field. The necessary conditions are found under which the structure behaves as a left-handed negative-index metamaterial. Analytical expressions for the frequency-dependent phase and group refractive indices are obtained.

1. Introduction

During the last years, the exotic behavior of electromagnetic waves (EMW) in so called left-handed media became an object of many interesting and outstanding investigations (see, for example, [1–11] and citations therein). In particular, a great effort has been made to predict theoretically and observe the negative refraction (NR) of the waves in various artificial materials including periodic multilayer nanostructures, where the waves have many unusual properties due to their specific dispersion characteristics. In Ref. [12], the problem of anomalous refraction has been studied in ferrite-semiconductor superlattices (SL) in the presence of an external magnetic field and has been shown that the latter influences considerably on the dispersion properties of the waves as well as on the number of the spectral branches and frequency regions of existence for the backward waves. On the other side, in the last several years there has been enormous interest in antiferromagnetic substances, which possess special optical and spintronic properties in terahertz frequency region. In spite of that, up to now there are only a few studies on the possibility of NR in periodic structures containing antiferromagnetic layers. In [13], the characteristics of the bulk EMW have been discussed in antiferromagnet/semiconductor SL in the absence of an external magnetic field.

The properties of the magnetic plasmon polaritons in homogeneous negative-index metallic antiferromagnets have been studied in [14].

The aim of this work is an investigation of the effect of an external static magnetic field on the behavior of EMW in periodic multilayer nanostructures consisting of alternating layers of antiferromagnetic insulator (for example, Cd$_{1-x}$MnxTe) and non-magnetic semiconductor (CdTe). When the characteristic dimensions of the layers are much smaller than the internal wavelength, the coexistence of both magnetic and plasmonic properties in such structures leads to the interesting peculiarities of the waves propagating in the backward regime. We shall examine the anomalous refraction of the coupled magnon–plasmon polaritons, that is, photons coupled with antiferromagnetic magnons and magnetoplasmons. As it is well known [15,16], this coupling is especially strong for the waves in THz region, when frequencies of the photons are comparable with the characteristic frequencies of the magnons and magnetoplasmons.

The paper is organized in five main sections. Section 2 describes the effective permittivity and permeability tensors of SL used for the analysis of the dispersion relations for the propagating waves. Section 3 discusses mixed magnon–plasmon polaritons in the case of the Voigt geometry when TE- and TM-type polarized waves propagate separately. The dispersion curves and frequency regions of existence are determined for TE waves, which can exhibit anomalous dispersion. In Section 4, the necessary conditions are obtained for absolute left-handed behavior of the medium with respect to the TE waves. In Section 5 the concluded remarks are highlighted.
where relative effective permittivity and permeability tensors read

$$
\tilde{\varepsilon}_{\text{ef}} = \begin{pmatrix}
\varepsilon_{11} & \varepsilon_{12} & 0 \\
\varepsilon_{12} & \varepsilon_{22} & 0 \\
0 & 0 & \varepsilon_{33}
\end{pmatrix},
\tilde{\mu}_{\text{ef}} = \begin{pmatrix}
\mu_{11} & \mu_{12} & 0 \\
-\mu_{12} & \mu_{22} & 0 \\
0 & 0 & \mu_{33}
\end{pmatrix},
$$

where

$$
\varepsilon_{11} = \varepsilon_{\infty} \left(1 - \frac{\alpha_{p}^{2}}{\omega^{2} - \alpha_{p}^{2}}\right),
\varepsilon_{22} = -\frac{\varepsilon_{\infty} \varepsilon_{0} \omega_{p}^{2}}{\omega (\omega^{2} - \omega_{p}^{2})},
\varepsilon_{33} = \varepsilon_{\infty} \left(1 - \frac{\alpha_{p}^{2}}{\omega^{2}}\right),
$$

$$
\omega_{p} = (Ne^{2}m_{0}q_{c}e_{p})^{1/2}
$$

is the plasma frequency, $\omega_{c} = eB_{0}/m$ is the cyclotron frequency, $e$, $m$, and $N$ are the charge, effective mass and density of the conduction electrons, respectively, $B_{0} = \mu_{0}H_{0}$, $e_{p}$ is the high-frequency dielectric constant, $\varepsilon_{0}$ and $\mu_{0}$, respectively, are permittivity and permeability of the free space.

An individual antiferromagnetic layer of thickness $l_{2}$ is described by a scalar dielectric constant $\varepsilon_{a}$ and permeability tensor [17,18],

$$
\tilde{\mu} = \begin{pmatrix}
\mu_{1} & i\mu_{2} & 0 \\
-i\mu_{2} & \mu_{1} & 0 \\
0 & 0 & 1
\end{pmatrix},
$$

where

$$
\mu_{1} = 1 + \alpha_{M}\varepsilon_{0} \left[\frac{1}{\omega_{r}^{2} - (\omega + \omega_{0})^{2}} + \frac{1}{\omega_{r}^{2} - (\omega - \omega_{0})^{2}}\right],
$$

$$
\mu_{2} = \alpha_{M}\varepsilon_{0} \left[\frac{1}{\omega_{r}^{2} - (\omega + \omega_{0})^{2}} - \frac{1}{\omega_{r}^{2} - (\omega - \omega_{0})^{2}}\right],
$$

$$
\omega_{0} = \gamma H_{0}, \alpha_{M} = \gamma H_{0}, \alpha_{0} = \gamma M_{s}, \gamma
$$

is the gyromagnetic ratio, $\omega$ is the angular frequency of the waves and

$$
\omega_{r} = \sqrt{\gamma H_{0}(\gamma H_{0} + 2H_{E})},
$$

is the antiferromagnetic resonance frequency in the absence of an external magnetic field. For most of known antiferromagnetic materials, this characteristic transverse magnon frequency is in the far infrared region. Inserting, for example, the following values:

$$
H_{E} = 550\text{kG},
H_{A} = 3.8\text{kG},
\gamma = 2.87\text{GHz/kg} (\text{MnF}_{2})
$$

from Eq.(4c) we obtain $\omega_{r} = 185.874\text{GHz}$.

Assuming that the period of the structure $d = l_{1} + l_{2}$ is much smaller than the internal wavelength and using method of effective anisotropic homogeneous medium [19,20,12], we obtain constitutive relations in the form

$$
\mathbf{D} = \varepsilon_{0}\varepsilon_{\infty}\varepsilon \mathbf{E},
\mathbf{B} = \mu_{0}\mu_{\infty}\mathbf{H},
$$

where relative effective permittivity and permeability tensors read

$$
\varepsilon_{\text{ef}} = \begin{pmatrix}
\mu_{11} & i\mu_{12} & 0 \\
-i\mu_{12} & \mu_{22} & 0 \\
0 & 0 & \mu_{33}
\end{pmatrix},
\mu_{\text{ef}} = \begin{pmatrix}
\mu_{11} & i\mu_{12} & 0 \\
-i\mu_{12} & \mu_{22} & 0 \\
0 & 0 & \mu_{33}
\end{pmatrix},
$$

The behavior of a monochromatic plane electromagnetic wave $\mathbf{E}, \mathbf{H} = \exp[i(k \mathbf{r} - \omega t)]$ in the medium described by Eq. (6) can be investigated using the Maxwell equations in the form

$$
[k \times \mathbf{E}] = \omega \mathbf{B},
[k \times \mathbf{H}] = -\omega \mathbf{D},
$$

Eliminating the magnetic field $H = (\mu_{0}\varepsilon_{\infty})^{-1}k \times \mathbf{E}$ from Eq. (7), for an arbitrary direction of the wave propagation $\mathbf{s} = k/k$ we obtain a set of equations

$$
(n^{2}\tilde{\eta} - \lambda m\tilde{\mu}_{\text{ef}})\mathbf{E} = 0,
$$

where $n = ck/\omega$ is the refractive index, $\tilde{\lambda}_{m} \equiv \mu_{11}\mu_{22} - \mu_{12}^{2}$, and

$$
\tilde{\eta} = \begin{pmatrix}
\mu_{11} S_{x}^{2} + \mu_{12} S_{y} S_{z} & -S_{x}(\mu_{11} S_{y} - i\mu_{12} S_{z}) & -S_{z}(\mu_{11} S_{y} - i\mu_{12} S_{z}) \\
-S_{x}(\mu_{11} S_{y} + i\mu_{12} S_{z}) & \mu_{22} S_{y}^{2} + \mu_{12} S_{x} S_{z} & S_{y}(\mu_{11} S_{x} - i\mu_{12} S_{z}) \\
-S_{z}(\mu_{11} S_{x} + i\mu_{12} S_{y}) & S_{y}(\mu_{11} S_{x} - i\mu_{12} S_{y}) & \mu_{11} S_{x}^{2} + \mu_{12} S_{y} S_{z}
\end{pmatrix}
$$

The system of equations (8) has a nontrivial solution only if the determinant of the coefficient matrix vanishes

$$
\text{Det}\ |n^{2}\tilde{\eta} - \lambda m(\tilde{\mu}_{\text{ef}})\mathbf{E}| = 0.
$$

Using Eqs. (9b) and (6) for the tensor $\tilde{\varepsilon}_{\text{ef}}$, we can write Eq. (10) in the form

$$
\text{An}^{4} - A_{\text{m}}B_{\text{m}}^{2} + \varepsilon_{33} \lambda \varepsilon_{m}^{2} = 0,
$$

where

$$
A = \lambda m(\varepsilon_{11} S_{x}^{2} + \varepsilon_{22} S_{y}^{2} + \varepsilon_{33} S_{z}^{2}) - 2\varepsilon_{0} H_{0} \varepsilon_{11} S_{x}^{2},
\lambda_{e} = \varepsilon_{11} e_{22} - e_{12}^{2},
$$

$$
B = \varepsilon_{33} \lambda m(\varepsilon_{11} S_{x}^{2} + \varepsilon_{22} S_{y}^{2}) + \lambda \varepsilon_{11} e_{22} + \varepsilon_{33}(\varepsilon_{11} e_{22} + \varepsilon_{22} \mu_{11} + 2\varepsilon_{0} H_{0} S_{y}^{2}).
$$

It follows that in the medium, two distinct extraordinary waves can travel whose refractive indices are given by solutions of

$$
\lambda m(\varepsilon_{11} S_{x}^{2} + \varepsilon_{22} S_{y}^{2}) + \lambda \varepsilon_{11} e_{22} + \varepsilon_{33}(\varepsilon_{11} e_{22} + \varepsilon_{22} \mu_{11} + 2\varepsilon_{0} H_{0} S_{y}^{2}).
$$
biquadratic equation (11). In general, for an arbitrary direction of propagation, both waves are elliptically polarized and correspond to the coupled magnon–plasmon polaritons. In the following, we will restrict ourselves by consideration of the propagating waves in the case of the Voigt geometry.

3. Coupled magnon–plasmon polaritons in the case of the Voigt configuration

Consider the propagation of the waves in the xy-plane perpendicular to the magnetic field, so as \( z_\perp = 0 \). In this case, the solutions of Eq. (11) are split in TM and TE waves with dispersion relations

\[
\eta_{TM}^2 = \frac{\lambda_2}{\mu_{11} S_2^2 + \mu_{22} S_2^2},
\]

and

\[
\eta_{TE}^2 = \frac{\lambda_2 \mu_{22}}{\mu_{11} S_2^2 + \mu_{22} S_2^2},
\]

respectively. Let us consider first the TM wave in which the magnetic field vector \( \mathbf{H} \) is parallel to the external field: \( \mathbf{H} = (0, 0, H) \). The electric field and time-averaged Poynting vector are given by

\[
\mathbf{E} = (\omega \mu_0 \lambda_{e}^{-1})(-\varepsilon_2 k_y - i \varepsilon_1 k_x - i \varepsilon_0 k_y, 0) \mathbf{H},
\]

\[
\mathbf{S} = (i \varepsilon_1 k_x, i \varepsilon_2 k_y, 0)(2\omega \mu_0 \lambda_{e}^{-1})|\mathbf{H}|^2,
\]

where

\[
k_2^2 = k_2^2 \lambda_x - \varepsilon_1 k_2^2 \lambda_2, \quad k_0 = \omega/c.
\]

Using Eqs. (16) and (17) we conclude that the dot product \( \mathbf{K} \cdot \mathbf{E} = \omega \mu_0 |\mathbf{H}|^2/2 \) is positive. It means that propagating TM waves are always forward, but it does not mean that the phenomenon of negative refraction is impossible. Indeed, consider the case when \( \varepsilon_1 > 0 \) while \( \varepsilon_2 \leq 0 \), so as \( \lambda_2 \) is negative. It is not difficult to see that if TM wave is incident from the vacuum onto the interface of the medium, the transmitted bulk wave exists for all possible angles of incidence and the Poynting vector of the refracted wave is in the same side of the normal to the interface as that in the incident wave. Therefore, the negative refraction of the TM waves occurs without backward waves. Such a possibility of negative refraction has been predicted in [21] for uniaxial nonmagnetic dielectrics with negative dielectric permittivity along the anisotropy axis.

It is important to note that TM waves correspond to the coupled plasmon polaritons without any mixture of the magnons. That is, why in the following we shall consider the peculiarities of the TE waves corresponding to the coupled magnon–plasmon polaritons, which are of interest in this work.

The field structure and time-averaged Poynting vector of the TE wave are given by

\[
\mathbf{E} = (0, 0, E_z), \quad \mathbf{H} = (\omega \mu_0 \lambda_{e}^{-1})(-\mu_2 k_y, \mu_1 k_x, 0) \mathbf{E},
\]

\[
\mathbf{S} = (\mu_1 k_x, \mu_2 k_y, 0)(2\omega \mu_0 \lambda_{e}^{-1})|\mathbf{E}|^2,
\]

where

\[
k_2^2 = k_2^2 \mu_3 \mu_r - \mu_{11} \mu_2 \mu_3^2 k_2^2,
\]

and

\[
\mu_r = \mu_2 / \mu_1 = \mu_1 - \frac{\mu_2^2}{\mu_2}.
\]

is the effective Voigt permeability. Using Eqs. (6b,6c), (2), (4a, 4b) and (9a), the dispersion relation (14) can be rewritten in the form

\[
\eta^2 = \frac{\varepsilon_0 \omega^2 - \varepsilon_0 \omega^2 (\varepsilon_0^2 - \varepsilon_0^2)}{\omega^2 (\varepsilon_0^2 - \varepsilon_0^2)},
\]

where

\[
\varepsilon_r = \frac{l_1 e_0 + l_2 e_0}{l_1 + l_2},
\]

\[
\varepsilon_p = \omega_p \left( 1 + \frac{2l_2 e_0}{l_1 e_0} \right)^{-1/2},
\]

is the effective plasma frequency.

\[
\omega_0^2 = \omega_0^2 + \omega_0 \omega_0 \pm \sqrt{(\omega_0 \omega_0)^2 (l_1/l_2)^2 + 4\omega_p^2 (\omega_0^2 + \omega_0 \omega_0)}.
\]

\( \beta \) is the angle between the wave vector \( \mathbf{k} \) and the positive y-axis: \( \tan \beta = k_0 / k_0 \), and

\[
\alpha^2 = \omega_0^2 + \omega_0 \omega_0 (1 + l_2/l_1) + \sqrt{(\omega_0 \omega_0)^2 (l_1/l_2)^2 + 4\omega_p^2 (\omega_0^2 + \omega_0 \omega_0) (1 + l_2/l_1)}.
\]

Using Eq. (21), it is easily seen that there are three branches in the spectrum of the TE waves, and in distinct ranges of the applied magnetic field these branches have different dispersion behaviors. In general, the magnetic fields can be divided into three different regions: “low” field \( (\omega_0 < \omega_0^2) \), “middle” \( (\omega_0^2 \leq \omega_0 < \omega_0^2) \) and “high” field \( (\omega_0 > \omega_0^2) \) regions. For a given direction of the wave propagation, the limits of these regions are defined by resonance frequencies at zero magnetic field

\[
(\omega_0^2)^2 = \omega_0^2 + \omega_0 \omega_0 (1 + \sqrt{1 - 4l_1 l_2 d^2 \sin^2 \beta}).
\]

In the “low” and “high” field regions, the wave has two resonance frequencies \( (n \to \infty) \) at \( \omega = \omega_0 \), and \( \omega = \omega_\perp \) while in the “middle” field regime there is only one resonance at \( \omega = \omega_0 \).

With increase in magnetic field, \( \omega_0 \) increases monotonically while \( \omega_\perp \) decreases in the range of the “low” fields, vanishes at \( \omega_0 = \omega_0^2 \), appears again at \( \omega_0 = \omega_0^2 \), and then increases approaching asymptotically the straight line \( \omega = \omega_0 \) in the range of the “high” fields (see Fig. 2, solid lines). Besides, the wave has three cutoff frequencies \( (n = 0) \) at \( \omega = \omega_0 \), and \( \omega = \Omega_\perp \). The dependence of \( \Omega_\perp \) on the magnetic field is shown schematically in Fig. 2 (dashed curves).

Note that the “middle” field region is very narrow: for MnF\(_2\), inserting in Eq. (26) \( l_1 = 1 \mu m, l_2 = 0.2 \mu m, \beta = \pi/6, \omega_0 = 1.722 \) GHz.
and using the parameter values given in Eq. (4d), we obtain
\[ \omega_0^p = 185.877 \text{ GHz}, \quad \omega_0^s = 185.971 \text{ GHz} \]  
(26a)
that is, 64.76 kG < \( H_0 \) < 64.80 kG. In spite of that, the "middle" field region should be divided in two parts
\[ \omega_0^p \leq \omega_0 < \Omega_{-} \]  
(27a)
and
\[ \Omega_{-} \leq \omega_0 \leq \omega_0^s \]  
(27b)
where
\[ \Omega_{-}^s = \sqrt{\omega_0^2 + 2 \omega_{A0} \omega_0 / d} \]  
(28)
is the cutoff frequency at zero magnetic field. An estimation for MnF\(_2\) gives \( \Omega_{-}^s = 185.891 \text{ GHz} \). In part I, the wave has three cutoff frequencies while in part II there are only two such frequencies.

In Fig. 3, the dispersion curves in the "low" field regime are shown schematically for three different values of the plasma frequency: \( \omega_p < \omega_- \) (Fig. 3a), \( \omega_- < \omega_p < \Omega_+ \) (Fig. 3b) and \( \omega_+ < \omega_p < \Omega_+ \) (Fig. 3c). The wave exists, as in the absence of the magnetic field, in three frequency regions, the limits of which are different for these three cases and also depend essentially on the magnetic field. Note that the dispersion of the high-frequency branch is normal in all these three cases while that for the low-frequency branch is anomalous \( \langle d\omega / dk \rangle < 0 \) in cases (b) and (c). As to the middle branch, it is normal in cases (a), (b) and anomalous in case (c). It is evident that left-handed behavior of the medium can only be expected in the frequency ranges corresponding to the branches with anomalous dispersion.

In Figs. 4 and 5, the dispersion curves of the TE wave are shown in the "middle" field regime for different values of the plasma frequency in part I [see Eq. (27a), Fig. 4] and part II [Eq. (27b), Fig. 5]. In the latter case, there are only two branches in the spectrum, and low-frequency branch possess anomalous dispersion only if the condition
\[ \omega_p < \omega_+ \]  
(29)
is fulfilled (see Figs. 5b, c). Note that in part I of the "middle" field range, there is only one branch with anomalous dispersion for \( \omega_+ \leq \omega_p \) (Fig. 4a) and two such branches for \( \omega_p > \omega_+ \) (Fig. 4b). Note also that unlike the cases shown in Figs. 3 and 5, the wave numbers for the low-frequency branch in Fig. 4a, b are restricted: \( k < k^- \), where
\[ \bar{k} = \omega_p (\bar{\epsilon}_0 \mu_0 \bar{\rho})^{1/2}, \quad \rho = \frac{(\omega_2^2 - \omega_0^2) (\omega_4^2 + 2 \omega_{A0} \omega_0 / d^2 - \omega_0^2)}{(\omega_2^2 - \omega_0^2) (\omega_4^2 - \omega_0^2) - 4 \omega_{A0}^2 \omega_0 / d^2 \sin^2 \beta} \]  
(30)
However, the last statement is only true if \( \omega_0 > \omega_p^2 \). At \( \omega_0 = \omega_p^2 \), the low-frequency branch exists for all possible wave numbers and approaches asymptotically to zero when \( k \to \infty \).

Finally, "high" field region should be divided in two subregions too: \( \omega_p^2 < \omega_0 \leq \omega_+ \) and \( \omega_0 > \omega_+ \), where
\[ \omega_1 = (\omega_2^2 + 2 \omega_{A0} \omega_0)^{1/2} \]  
(31)
is the frequency of the longitudinal optical magnons at zero magnetic field. Substituting in Eq. (31) \( \omega_T = 185.874 \text{ GHz} \), \( \omega_A = 10.906 \text{ GHz} \) and \( \omega_K = 1.722 \text{ GHz} \) (MnF\(_2\)), we obtain \( \omega_p = 185.975 \text{ GHz} \). The wave has two cutoff frequencies in the first part and three in the second one. In Fig. 6, the dispersion curves are shown in both these subregions for the case when \( \omega_+ < \omega_p < \Omega_+ \). Note that in the frequency range \( \omega_+ < \omega < \omega_p \) there is only one branch with anomalous dispersion, and low-frequency branch in the case of Fig. 6a exists only if the wave number \( k > k^- \), where \( k^- \) is given by Eq. (30).

The estimated values of the resonance, cutoff and cyclotron frequencies are shown in Table 1.
4. Necessary conditions for the negative refraction of the TE waves. Phase and group refractive indices

Suppose now that TE type polarized plane wave $\mathbf{E}, \mathbf{H} = \exp[i(k_0 x + k_0 y - \omega t)]$ is incident from the vacuum onto the interface of the medium. For a given value $\alpha$ of the angle of incidence, $k_0 = k_0 \sin \alpha$ and $k_0 = k_0 \cos \alpha$. Inside the medium, the refracted wave propagates as mixed magnon–plasmon polariton of the same polarization.

Using Eqs. (19) and (20), for the dot product of the wave and Poynting vectors we obtain

$$k_S = \frac{(\mu_1 k_0^2 + \mu_2 k_0^2)}{2\alpha_0 \alpha_0} |E|^2 = \frac{1}{2} \alpha_0 \alpha_0 |E|^2.$$  

Taking into account that the energy flux for the refracted wave is always directed away from the interface ($k_0 > 0$), we conclude that the wave is backward with respect to the interface (i.e., the phase velocity is directed to the interface) only if the condition $\mu_1 < 0$ is fulfilled. At this end, the medium is left-handed with respect to the wave (i.e., $k_S < 0$), if

$$\alpha_0 < 0,$$

and the negative refraction occurs if

$$\mu_1 \mu_2 > 0.$$

Except that, the condition of existence for the refracted wave ($k_0^2 > 0$) must be fulfilled

$$\alpha_0 \mu_2 > \frac{\mu_1}{\mu_2} \sin^2 \alpha.$$  

All these four conditions (33a–d) can only be fulfilled simultaneously within the frequency bands of anomalous dispersion. The corresponding situation in Ref. [13] has been termed as the case of absolute left-handed medium. The mutual orientation of the wave and Poynting vectors in this case is illustrated schematically in Fig. 7. The angles of refraction for the wave and Poynting vectors are given by Snell’s law $\sin \beta = n_p^{-1} \sin \alpha$ and $\sin \gamma = n_g^{-1} \sin \alpha$, respectively, where

$$n_p = \sqrt{\varepsilon_0 \varepsilon_f + (1 - \mu_1/\mu_2) \sin^2 \alpha}$$  

is the phase refractive index and

$$n_g = -\sqrt{\varepsilon_0 \varepsilon_f (\mu_2/\mu_1)^2 + (1 - \mu_2/\mu_1) \sin^2 \alpha}$$  

is the group refractive index. The angle $\phi$ between the wave and Poynting vectors is given by

$$\cos \phi = \frac{\sin^2 \alpha + \sqrt{(n_p^2 - \sin^2 \alpha)(n_g^2 - \sin^2 \alpha)}}{n_p n_g}$$

and is always obtuse if the conditions (33a–d) are fulfilled.
frequency ranges and different regimes of the applied field. In general, the behavior of the wave depends on the sign of the Voigt permeability, diagonal components of the effective permeability tensor in the plane perpendicular to the applied field and effective permittivity \( e_{33} \) along the field direction. It is shown that the wave is backward and can be refracted negatively if the following conditions are fulfilled simultaneously: (a) \( e_{33} \) should be negative; (b) instead of the scalar permeability in isotropic case, the effective Voigt permeability must be negative; (c) the additional conditions (33c,d) should be fulfilled too. We have shown also that the structure with negative permeability along the normal to the interface can achieve negative refraction with respect to the TE wave even when the wave is forward.

The main properties of the wave, in particular, the number of the frequency bands of propagation, their limits and width, as well as the number of the branches with anomalous dispersion are quite different in various ranges of the applied magnetic field and therefore can be changed using the latter as a tuning parameter. It is remarkable that the limits of the frequency regions of the anomalous refraction are very sensitive not only to the applied field but also to the effective plasma frequency. This fact opens possibility for control of the regions using the samples with different values of the free charge carrier’s density in the semiconductor layers.
